How to run the code

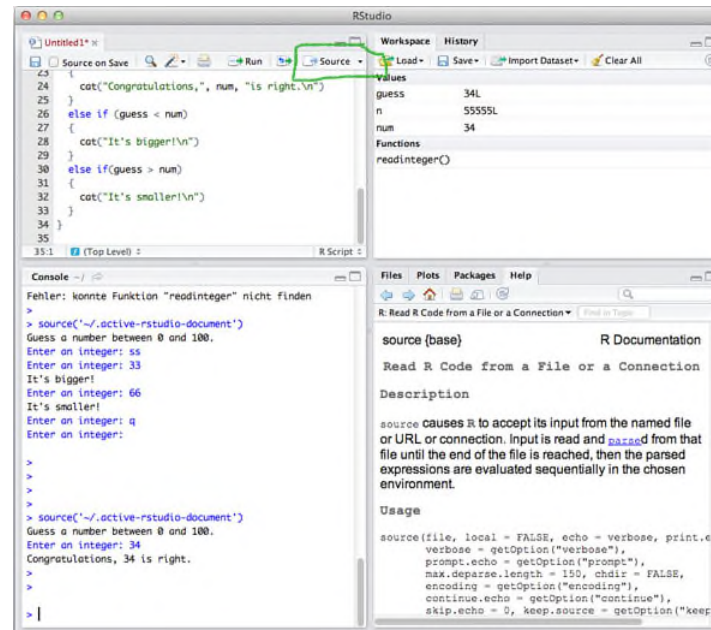

I find it easiest to use [RStudio](#). You can also paste the code in a normal R console or let R run a source file. However these approaches are a bit less fail-safe.

Using RStudio

Download and install [RStudio](#).

Open RStudio and do this:

1. Click on the menu: File -> New -> R Script
2. Paste the code in the new source code area
3. Click the "Source" button above the code area:

You can also use the console in RStudio. If you click "Run" instead of "Source" user input might not work properly.

You can use the R documentation like this: `help(function.name)`.

Using the R console

Running the `r` program on the command line or elsewhere will start the console. You can paste your code there.

Problems with this approach

This will generally work if you use `source("filename.r")` to run your code. If you paste the code some of it might be read as user input.

[RStudio IDE](#)

Made by Matt Zeunert

Running a source file with R

You can run a source file like this: `r -f filename.r`.
R also provides a lot of [other command line arguments](#).

Problems with this approach

I have not managed to get user input to work here.
